

A Formal Connection between Security Properties and JML Annotations

Work in progress with Marieke Huisman

Alejandro Tamalet
Radboud University
Nijmegen, The Netherlands

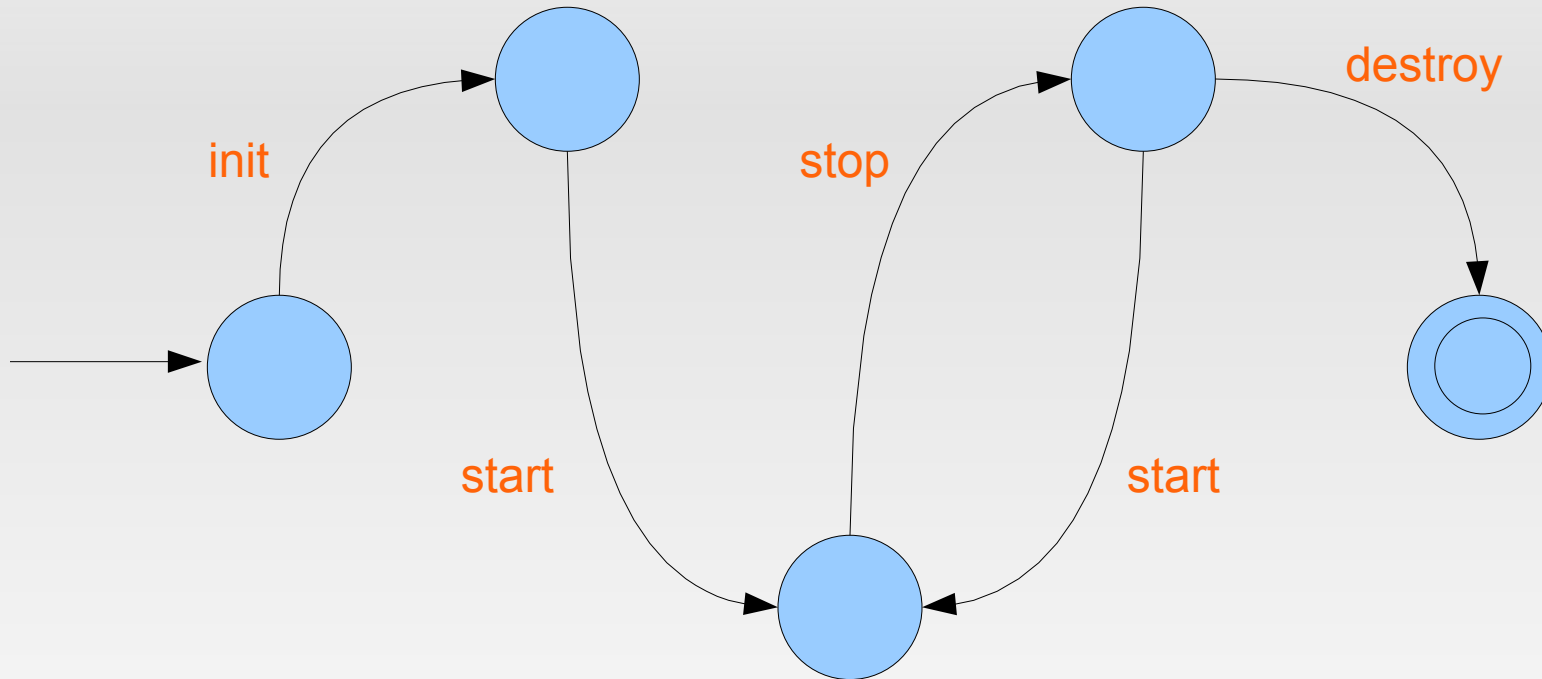

Introduction: The Goal

- Trusted devices (smart phones, PDA, smart cards) need a way to ensure the **security** of applications.
- We want to **enforce** (at runtime) a certain property. Ultimately, we would like to **prove** (statically) that it holds.
- We will work with **Java or Java-like** sequential programs.

Introduction: The Means

- One way to achieve this goal is to **encode the property as JML annotations**
- JML connects runtime checking (jmlc) and proving (ESC/Java2).
- This imposes restrictions on the kind of properties we can express: only **safety properties** (no liveness).

Example: An applet protocol as an automaton (Cheon and Perumendla)

init; (start; stop)+; destroy

Example: The applet protocol specified in JML (Cheon and Perumendla)

```
package java. applet

public class Applet {
    /*@ public static final ghost int
       @   PRI STI NE = 1,
       @   I NI T = 2,
       @   START = 3,
       @   STOP = 4,
       @   DESTROY = 5;
       @*/

    //@ public ghost int state = PRI STI NE;

    //@ requires state == PRI STI NE;
    //@ ensures state == I NI T;
    public void init() {
        //@ set state = I NI T;
        ...
    }

    //@ requires state == I NI T || state == STOP;
    //@ ensures state == START;
    public void start() {
        //@ set state = START;
        ...
    }

    //@ requires state == START;
    //@ ensures state == STOP;
    public void stop() {
        //@ set state = STOP;
        ...
    }

    //@ requires state == STOP;
    //@ ensures state == DESTROY;
    public void destroy() {
        //@ set state = DESTROY;
        ...
    }
}
```

Multi-Variable Automata (MVA)

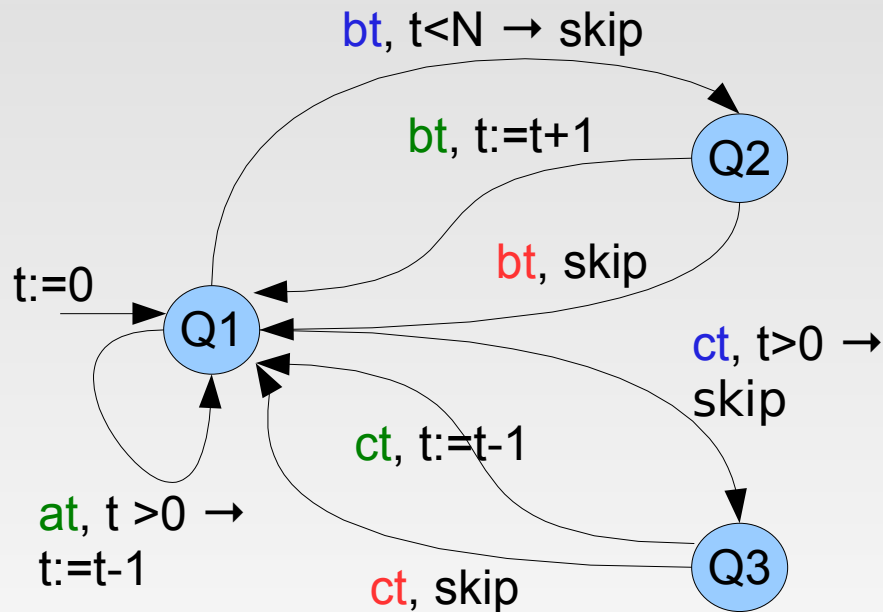

- We want to **keep the high level view** of these properties.
- **Regular automata are not enough** to express many interesting properties. We use **automata with variables**.
- An automaton specifies a property of a class called the **monitored class**.

Transitions

- **Transitions** of an MVA have an event, a guard and actions.
- The **events** can be **entry** to or exit of methods. We distinguish between a **normal exit** and an **exceptional exit**.
- **Guards** and **actions** may involve fields of the monitored class or parameters of the method. Actions can only update variables of the automaton.

Example: Embedded transactions

Property: At most N embedded transactions.

bt = beginTransaction()
ct = commitTransaction()
at = abortTransaction()

entry

exit normal

exit exceptional

Automaton:

Monitored class: transactions.java

$Q = \{Q1, Q2, Q3\}$

$\Sigma = \{bt, bt, bt, ct, ct, ct, at\}$

$vars_A = \{(t, \text{int}, 0)\}$

$vars_P = \{\}$

Other properties

- Enforce and order in which methods are called: **life cycle** or **protocol** of an object.
- Restrict the **frequency** of a particular method call.
Example: `m()` can be called at most one time.
- Method `m1()` can not or can only be called **inside** method `m2()`.

Characteristics of a MVA

- The automaton must be **deterministic**.
- We **complete** the transition function by adding an error state. We call it **halted**.
- Since we work with safety properties, halted is a **trap state**.
- We don't have **accepted states**.

Abstract correctness property

P = program (may already have annotations)

A = automaton describing a security property

\parallel = monitored by

\approx = equivalence relation

Assumptions: P does not throw nor catch JML exceptions

A is “*well formed*” and “*well behaved*”

$$P \parallel A \approx \text{ann_program}(P, A)$$

Translation into JML... plus some code transformations

- Some **code transformations** are needed to treat exceptions. We have to enclose the body in a `try-catch-finally` block.
- If no code transformations are allowed we must **restrict the expressiveness** of the automata. We would only be able to talk about entry to methods.

ann_program: Two step translation

- For the following algorithm, we focus more in its **correctness** than in its actual implementation.
- For ease of verification, the translation is done in **two steps**. In the first step we do some **abstractions** and then we **refine** them in the second step.

Step 1 – 1: Add ghost variables

- New ghost variables are added to encode the automaton.
 - Control points (including **halted**): integers initialized to a unique value.
 - Current control point (**cp**): integer initialized to the value of the initial control point.
 - Variables of the automaton: their type and initial value are provided by the automaton.

Step 1 – 1: Example

```
/* @ public static final ghost int  
   @ HALTED = 0,  
   @ Q1 = 1,  
   @ Q2 = 2,  
   @ Q3 = 3;  
   @ */
```

```
// @ public ghost int cp = Q1;
```

```
// @ public ghost int t = 0;
```

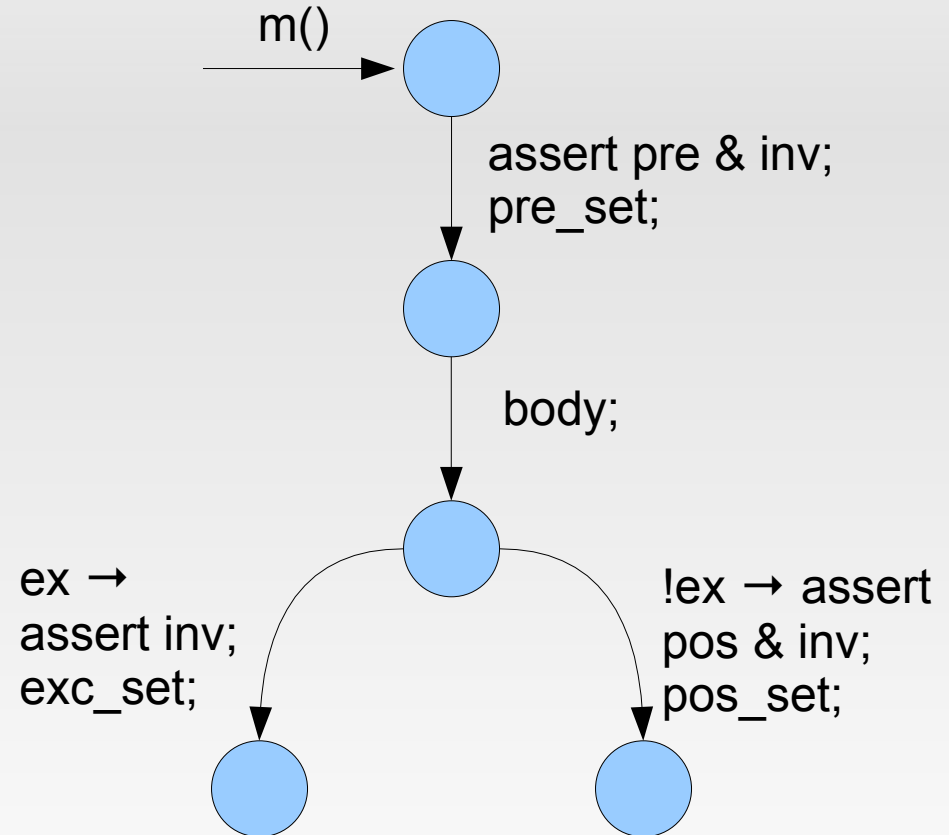

Step 1 – 2: Strengthen invariant

- The **invariant is strengthened** to assert that the current control point has not reached the error state.

```
// @ public invariant cp != halted;
```

Step 1 – 3: Annotate methods

```
// @requires pre;  
// @ensures pos;  
m() {  
  pre_set {  
    /* @ annotations regarding  
       ms entry @ */  
  } body {  
    ms body  
  } pos_set {  
    /* @ annotations regarding  
       ms normal exit @ */  
  } exc_set {  
    /* @ annotations regarding  
       ms exceptional exit @ */  
  }  
}
```

Step 1 – 4: Translate events

- Each transition is translated **independently** of the type of its event (entry, exit normal or exit exceptional).
- We assume the existence of an **i f** statement that works with **ghost variables** in the condition and in the branches.

Step 1 – 4: Example at

```
/*@ if (cp == Q1) {  
  @ if (t > 0) {  
    @ set t = t - 1;  
    @ set cp = Q1;  
    @ } else {  
      @ set cp = HALTED;  
    @ } else if (cp == Q2) {  
      @ set cp = HALTED;  
    @ } else if (cp == Q3) {  
      @ set cp = HALTED;  
    @ } else { // cp == HALTED  
      @ set cp = HALTED;  
    @ }  
  @ }  
@*/
```

```
/*@ if (cp == Q1 && t > 0) {  
  @ set t = t - 1;  
  @ set cp = Q1;  
  @ } else {  
    @ set cp = HALTED;  
  @ }  
@*/
```

Step 2 – 1: Refine **if** - 1

- The **if** for ghost variables are translated into a sequence of **set** statements using **conditional statements**.

```
if ( c ) {  
    set x := a;  
    set y := b;  
}
```

```
set x := c ? a : x;  
set y := c ? b : y;
```

Step 2 – 1: Refine **if** - 2

- Two **auxiliary ghost variables** are used to ensure the independence of the branches.

```
if (cp == Q1) {  
  if (x >= 5) {  
    set x = x-1;  
    set cp = Q2;  
  } if (x < 0) {  
    set x = x+1;  
    set cp = Q1;  
  } else {  
    set cp = HALTED;  
  }  
}
```

```
set b1 = cp == Q1;  
set b2 = b1 && x >= 5;  
set x = b2 ? x-1 : x;  
set cp = b2 ? Q2 : cp;  
set b2 = b1 && !b2 && x < 0;  
set x = b2 ? x+1 : x;  
set cp = b2 ? Q1 : cp;  
set b2 = b1 && !b2;  
set cp = b2 ? HALTED : cp;
```

Step 2 – 2: Refine pre_set et al.

```
m() {  
    // @ghost boolean ex;  
    try {  
        // @pre_set;  
        // @assert cp != halted;  
        body  
    }  
}
```

```
catch (Exception e) {  
    // @exc_set;  
    // @set ex = true;  
    throw e;  
} finally {  
    // @if (!ex) { pos_exc; }  
}  
}
```

Example: translation of the embedded transactions

```
public void beginTransaction() {  
    // @ghost boolean ex;  
    try {  
        // @set cp = (cp == Q1 && t < N) ? Q2 : HALTED;  
        // @assert cp != HALTED;  
        body  
    } catch (Exception e) {  
        // @set cp = (cp == Q2) ? Q1 : HALTED;  
        // @set ex = true;  
    } finally {  
        // @set t = (!ex && cp == Q2) ? t+1 : t;  
        // @set cp = (!ex && cp == Q2) ? Q1 : HALTED;  
    }  
}
```

Formalization

- Everything must be **defined**:
 - Automata and their operational semantics.
 - (A subset of) Java programs with annotations and their operational semantics (big step, based on Von Oheimb's formalization).
 - A semantics for monitored programs.
 - A bisimulation relation.

- Provides an expressive specification language an interactive proof checker and other tools for managing and analysing specifications.
- Its logic is an extension of higher order logic with support for predicate subtyping and dependent types.
- Does not provide polymorphic types but theories are parametrizable.

A subset of Java-like programs - 1

- We formalized the syntax and semantics of a subset of Java relevant for our problem.
 - Types: int, boolean, void, references.
 - Exceptions: Throwable, NullPointerException, JMLExc
 - Expressions: method calls, assignments, etc.
 - Statements: if, while, try-catch-finally, etc.
 - Annotations: set, assert, requires, ensures, invariant.

A subset of Java-like programs - 2

- We did some typical simplifications.
 - Methods have only one argument
 - Local variables declared at the beginning
 - No `return` instruction
- Some things were not modelled.
 - Only basic things of the inheritance apparatus were modelled (method lookup)
 - Static fields, static overloading, initialization

Characteristics of the specification - 1

- To deal with **termination**, the semantics requires the length of the derivation sequence.
- We have one **parametric** semantics that we instantiate to get the behaviour of annotated programs and (annotated) monitored programs.

Characteristics of the specification - 2

- The **syntax of programs** is described by a datatype with mutually recursive subtypes:

```
Body[ Name: TYPE+ ] : DATATYPE WITH SUBTYPES Expr, Stmt  
  Assign(target: Name, source: Expr): Assign? : Expr  
  While(test: Bool Expr, body: Stmt): While? : Stmt
```

- This allows us to have only one semantic function instead of two mutually recursive functions: one for expressions and one for statements.

Characteristics of the specification - 3

- The functions passed as parameters to the semantics theory to define `derive` need a way to do their own computations.
- PVS does not provide built-in support for mutual recursive functions. They are emulated by passing functions as arguments.

```
derive_type(n: nat): TYPE = [ FullProgram →  
  [ Body, FullState, Val, FullState → [ below(n) → bool ] ] ]  
derive_rec_type(n: nat): TYPE =  
  [ k: upto(n) → derive_type(k) ]
```

States

`MnitoredProgram TYPE = [# mva: MVA, program Program #]`

`Store: TYPE = [Name -> Val]`

`AState: TYPE = [# cp: CP, stA: Store #]`

`PState: TYPE = [# ex: lift[Excpt], fvs, lvs: Store #]`

`APState: TYPE = PState WITH [# gvs: Store #]`

`MPState: TYPE = APState WITH [# astate: AState #]`

The equivalence relation - 1

$\text{MVA_model_ed?}(\text{mp})(\text{sA: AState}, \text{sAP: APState}): \text{boolean} =$
 $\text{MVA_cp_model_ed?}(\text{mp})(\text{sA}, \text{sAP}) \text{ AND}$
 $\text{MVA_cps_model_ed?}(\text{mp})(\text{sAP}) \text{ AND}$
 $\text{MVA_vars_model_ed?}(\text{sA}, \text{sAP})$

$\text{Program_model_ed?}(\text{sMP: MPState}, \text{sAP: APState}): \text{boolean} =$
 $\text{pstate}(\text{sMP}) = \text{pstate}(\text{sAP}) \text{ AND}$
 $\text{Program_gvs_model_ed?}(\text{sMP}, \text{sAP})$

The equivalence relation - 2

$\text{halted_implies_JMLExc}(mp)(sMP: MPState, sAP: APState): \text{boolean} =$
 $\text{cp}(\text{astate}(sMP)) = \text{halted_IMPLIES}$
 $(\text{up?}(\text{ex}(\text{pstate}(sAP)))) \text{ AND } \text{down}(\text{ex}(\text{pstate}(sAP))) = \text{JMLExc})$

$\text{related_states}(mp)(sMP: MPState, sAP: APState): \text{boolean} =$
 $\text{wf_state}(mp)(sMP) \text{ AND}$
 $\text{wf_state}(\text{ann_program}(mp))(sAP) \text{ AND}$
 $\text{MP_model ed?}(mp)(sMP, sAP) \text{ AND}$
 $\text{halted_implies_JMLExc}(mp)(sMP, sAP)$

Correctness property in PVS

correctness_of_ann_program : THEOREM

FORALL (mp) (main : Method, arg : int)

(sMP : MPState, sAP : APState) :

well_behaved_MP(mp) IMPLIES

run_monitored_program(mp) (main, arg)

(sMP) IMPLIES

run_annotated_program(ann_program(mp)) (main, arg)

(sAP) IMPLIES

related_states(mp) (sMP, sAP)

The invariant

`derive_maintains_related_states` : THEOREM

FORALL (mp) (b: Body, v1, v2: Val)

(sMP1, sMP2: MPState, sAP1, sAP2: APState)

(n1, n2 : nat):

`well_behaved_MP`(mp) IMPLIES

`related_states`(mp) (sMP1, sAP1) IMPLIES

`derive`(mp) (b, sMP1, v1, sMP2) (n1) IMPLIES

`derive`(`ann_program`(mp)) (b, sAP1, v2, sAP2) (n2) IMPLIES

`related_states`(mp) (sMP2, sAP2) AND v1 = v2

Sketch of the proof of **step 1**

- The initial states are equivalent.
- Prove `derive_maintains_related_states`.
 - The proof is by induction on the length of the derivation sequence.
 - The method call case is the interesting one. Here is where we have to show that `ann_program` is correct.
- Prove `correctness_of_ann_program`

Advantages of having a formalization - 1

- Although the ideas are simple we found many **subtleties**.
 - `assert t` at the end of the `pre_set`.
 - in the proof the `try-catch-finally` case is tricky.

Advantages of having a formalization - 2

- Makes all the **requirements** explicit.
 - No clash between variable names of the automaton and the monitored class.
 - The evaluation of expressions appearing on guards or actions can not have side effects nor throw exceptions.
 - There must be an injective function from the set of control points to `int`.

Future work

- Prove the correctness of the **second step**.
- Generate preconditions and postconditions.
- Prove that some properties can be checked **statically**.
 - Extend the propagation algorithm given by Mariela Pavlova.
 - Formalize it in PVS by extending this work and prove its correctness.
